Abstract Coastal cutthroat trout (*Oncorhynchus clarkii clarkii*), native to the west coast of North America, has declined over much of its range. Population genetic studies can aid conservation, but few suitable markers have been available. We describe 62 novel single nucleotide polymorphism (SNP) markers variable in coastal cutthroat trout. We additionally show that 22 SNPs previously identified in other taxa are also polymorphic in the subspecies. These 84 SNP assays are the first to be developed for coastal cutthroat trout and will be a useful tool in coastal cutthroat trout management.

Keywords Single nucleotide polymorphism · Coastal cutthroat trout · *Oncorhynchus clarkii*

The cutthroat trout (*Oncorhynchus clarkii*) of North America comprises nine extant subspecies (Behnke 2002). Coastal cutthroat trout (*O. c. clarkii*), native to Pacific drainages from northern California to Alaska, is the most widespread subspecies and the sole one with an anadromous form (Trotter 1989). It has declined throughout much of its range,

primarily due to habitat loss (e.g. Wofford et al. 2005). Additionally, coastal cutthroat trout can hybridize with sympatric steelhead (*O. mykiss*), and habitat disturbance may break down barriers to gene flow (e.g. Bettles et al. 2005).

Population genetic studies are important for coastal cutthroat trout management. Genetic markers currently available are limited to allozymes and relatively few microsatellites, largely developed for other taxa (Wenburger et al. 1996; Condrey and Bentzen 1998). Markers that detect introgression of *O. mykiss* into cutthroat trout populations have recently been developed (e.g. Pritchard et al. 2012). Here, we describe a suite of 84 single nucleotide polymorphisms (SNPs) that are variable within multiple populations of coastal cutthroat trout.

Protocols for SNP discovery, TaqMan assay design, and SNP genotyping were as described in Pritchard et al. (2012 and 2013). The ascertainment panel (Pritchard et al. 2012) contained both *O. clarkii* and *O. mykiss* and included samples from four coastal cutthroat trout populations: Slippery Lake, Alexander Archipelago, Alaska (n = 1); Abernathy Creek, Columbia River, Washington (n = 1); Mill Creek, Columbia River, Washington (n = 1) and Little Creek, California (n = 2). SNPs containing an allele rare in *O. c. clarkii* but common in *O. mykiss* were considered indicative of recent introgression and excluded from assay design. Assays were validated using 184 coastal cutthroat trout from 8 populations across the subspecies' range (Table 1).

Seven SNPs diagnostic between *O. mykiss* and other cutthroat subspecies but known to be polymorphic in coastal cutthroat trout were included in the validation step (Pritchard et al. 2012). Additionally, assays interrogating SNP sites within *O. mykiss* (n = 136, Abadía-Cardoso et al. 2011; Aguilar and Garza 2008), and other *O. clarkii* subspecies (n = 179, Campbell et al. 2012; Pritchard et al. 2013), were screened with 14–23 coastal cutthroat trout

^a SNP discovery described in Pritchard et al. (2013)

from California and Washington. Polymorphic SNPs were subsequently genotyped over the wider validation panel.

Observed (H_o) and unbiased expected heterozygosity (H_e) were calculated using Genetix (Belkhir et al. 2001). Deviations from Hardy–Weinberg and linkage equilibria were investigated using exact tests in Genepop (Raymond and Rousset 1995), applying the FDR correction (Benjamini and Hochberg 1995).

Of 242 primer pairs, 171 produced high-quality sequence for coastal cutthroat trout, generating 90,730 consensus base-pairs for a mean of 4.4 individuals per locus. There were 414 polymorphic sites observed, distributed over 130 loci and including 44 indels. Assays were successfully

designed for a SNP in 71 of these loci (Table 2). Nine assays were rejected following validation due to lack of polymorphism or problems calling genotypes.

Twelve SNPs previously developed for *O. mykiss* (8.8 % of those tested), six SNPs developed for *O. c. henshawi* (7.7 %) and three SNPs from other cutthroat trout subspecies were variable in initial screening samples and included in validation. Six were subsequently rejected due to calling problems. Two of the 15 retained assays (Table 1b) were physically linked to SNPs developed for coastal cutthroat trout: Omy_117540-259, 158 bp from Ocl_117540c; and Omy_97865-196, 107 bp from Ocl_97865c.

Following FDR correction, we observed only three significant deviations from Hardy–Weinberg equilibrium amongst the final set of 84 assays, at three different loci (Table 1). We observed one significant deviation from linkage equilibrium: Ocl_117370c–Ocl_124454c within Gines Creek.

The 62 novel SNP assays described here are the first to be developed for coastal cutthroat trout. Together with the seven species-diagnostic SNPs known a priori to be variable in coastal cutthroat trout, and the 15 SNPs developed for other taxa, they will be useful for population genetic studies throughout the subspecies' range. Blast searches showed 70 of these 84 SNPs to be in a locus with a putative function, and seven are non-synonymous substitutions (Supplementary Table 1).

Validation of the novel SNPs revealed comparable genetic diversity in Washington, Oregon and California populations, but reduced diversity in British Columbia and Alaska. Only one Alaskan individual was in our ascertainment panel; thus, reduced diversity in northern populations may represent ascertainment bias. However, it may also reflect recent colonization of previously glaciated areas. Supporting this, the 22 SNPs not identified from our ascertainment panel also had reduced diversity at higher latitudes. A similar latitudinal trend has been documented in *O. mykiss* (McCusker et al. 2000).

Approximately 6 % of the *O. mykiss* SNPs screened were polymorphic and reliably scored in coastal cutthroat trout. The relatively high minor allele frequencies for these SNPs indicate that they represent shared polymorphisms rather than *O. mykiss* polymorphisms introduced by hybridization. A similar proportion of SNPs variable in Lahontan cutthroat trout were polymorphic in coastal cutthroat trout (5.7 %, Pritchard et al. 2013). Thus, polymorphic sites are only rarely shared between species and subspecies.

Only one significant deviation from linkage equilibrium was observed in our dataset, despite the inclusion of two physically linked SNP pairs, which may reflect the relatively low power of the corrected test. Current efforts to map loci containing these SNPs will provide further information on physical linkage.

Acknowledgments We thank Denise Hawkins, Tish Osborne, Carl Ostberg, Dennis Shiozawa, Christian Smith and Andrew Whiteley for providing samples, and the SWFSC Molecular Ecology and Genetic Analysis team for assistance.
